

UX Interview Response — Basketball Player Participant

Scenario: I have knee pain after training and I want to log it, then check my recovery overview.

1. What do you think this application is for?

From the first look, I think this app is for athletes who want to track injuries, pain levels, and recovery progress. It feels like something I would use after training or a game when I have knee, ankle, shoulder, or back pain and want to keep track of how it changes over time.

The 3D body map makes the idea clear because I can visually connect the pain to a body part instead of just writing it in a normal note app.

2. After logging in, where would you click first?

After logging in, I would probably click **"Open 3D Body Map"** on the dashboard because it stands out and sounds like the main feature.

The sidebar also has **"3D Body Map"**, so I understand there are two ways to get there. That is good because I do not feel lost.

3. Is it clear how to open the 3D Body Map?

Yes, it is clear. The button on the dashboard helps a lot. Without that button, I might still find it from the sidebar, but the dashboard button makes the flow easier.

I like that the dashboard gives me a quick overview first, but still guides me toward the main action.

4. Is it clear that body parts are clickable?

Mostly yes, but because this is a low-fidelity wireframe, I cannot fully see which exact body parts are clickable. The text says **"Clickable body zones"** and **"Click a body part to view or log pain,"** so I understand the idea.

But in the final design, I would expect the body model to visually show clickable areas, maybe with hover highlights or colored zones. For example, if my knee is

painful, I want to clearly see that I can click the knee area.

5. What do you expect to happen after clicking a body part?

If I click the left knee, I expect a panel to open showing:

The selected body part, current status, pain level, recovery status, previous logs, and a button to add a new log.

That is exactly what I see in the wireframe, so the interaction makes sense. I also expect the body part to become highlighted on the 3D model, maybe with a color like yellow, orange, or red depending on the pain level.

6. Is the Add Injury Log modal easy to understand?

Yes, the modal is simple and easy to understand. I can see that I need to choose a pain level, injury status, recovery status, and add notes. The **Save Log** button is clear.

As a basketball player, I like that the pain level is from 0 to 10 because that is easy to understand after training. The previous logs inside the modal are also useful because I can compare today with earlier days.

One small issue: I would like the modal to make it clearer that I am logging pain for the **left knee**. It says left knee under the title, which is good, but maybe it could be more visually emphasized.

7. Are the fields in the injury log form enough, or is something missing?

The fields are enough for a basic MVP, but I would personally want a few extra fields.

I would add:

- **Activity type:** training, match, gym, running, warm-up, recovery session.
- **Cause or moment:** happened during jumping, landing, sprinting, contact, or after training.
- **Training intensity:** light, medium, hard.
- **Pain type:** sharp, dull, swelling, stiffness, tightness.
- **Can I train?:** yes, reduced intensity, no.

For basketball, this matters because knee pain after a game is different from pain after gym or after landing badly from a jump.

8. Is the dashboard useful, or does it show too much information?

The dashboard is useful. I like seeing active injuries, average pain level, recovery progress, and injury risk quickly. That gives me a fast overview before I decide if I should train hard or take it easier.

It does not show too much information. It is actually quite balanced. But I think the **Injury Risk: Low** card should explain why the risk is low. For example, is it based on pain level, number of logs, recovery status, or training load?

The recent injury logs are useful, but maybe the dashboard could also show the most important warning first, like:

“Left knee pain increased over the last 3 logs.”

That would be very useful for an athlete.

9. Is the injury history timeline easy to scan?

Yes, it is easy to scan. I like that each log card shows the date, body part, status, note, and pain level. The pain level on the right side is very visible, which is good.

However, the timeline could become long if I use the app every week. Filters are a good idea, but I would also like colors for status. For example:

Green for recovered, yellow for light pain, orange for moderate, red for high pain, blue for recovering.

That would make it faster to scan without reading every card.

10. Does the weekly report explain the data clearly?

Yes, the weekly report is clear. I understand the average pain, new logs, recovery progress, and risk level. The summary sentence at the top is helpful because it explains the report in normal language.

The **Smart Recovery Suggestions** section is also useful, especially because it gives simple advice like reducing training intensity. As a basketball player, that is helpful because I do not always know when pain is becoming a problem.

But I would be careful with the wording. It should not sound like medical advice. It should say things like "consider reducing intensity" or "monitor this area," not "you should do this treatment."

The disclaimer at the bottom helps make that clear.

11. Does the app feel like self-tracking instead of medical diagnosis?

Yes, mostly. It feels like a self-tracking tool because I am logging pain, checking progress, and reviewing trends. It does not feel like the app is diagnosing me.

The disclaimer on the login screen and weekly report helps. The phrase "**This is not a medical diagnosis tool**" is important.

The only area to be careful with is **Smart Recovery Suggestions**. That section should stay simple and general, otherwise it might feel too medical.

12. What would you improve first?

The first thing I would improve is the **3D Body Map interaction**. Since that is the main feature, I would make it very clear which body parts are clickable. I would add hover effects, selected body part highlighting, and color-coded pain status directly on the body model.

Second, I would improve the injury log form by adding activity context. For basketball, I need to know whether the pain happened after a game, gym session, sprint, jump, or contact.

Third, I would make the dashboard more action-focused. Instead of only showing numbers, it could tell me what changed since last week and what I should pay attention to.

Top 3 Improvements I Recommend

1. Make the 3D body model more obviously interactive

Add visible clickable zones, hover highlights, selected body part highlighting, and color-coded pain areas.

2. Add more sports context to the injury log form

Include activity type, training intensity, pain type, and when the pain happened.

3. **Make dashboard insights more actionable**

Add simple messages like "Left knee pain increased this week" or "Recovery improved compared to last week." This would help athletes understand what the data means faster.
