

Soccer Player UX Feedback — InjuryVision 3D

1. What do you think this application is for?

As a soccer player, I understand that this app is for tracking pain, injuries, and recovery after training or matches. It looks like I can log pain in a specific body part, like my knee, ankle, hamstring, or lower back, and then check if the pain is improving over time.

It feels more like a recovery tracking tool than a medical app, which is good.

2. After logging in, where would you click first?

After logging in, I would probably click **"Open 3D Body Map"** on the dashboard because it stands out clearly. The button is easy to notice.

The sidebar also has **"3D Body Map"**, so I understand there are two ways to reach the same main feature.

3. Is it clear how to open the 3D Body Map?

Yes, it is clear. The dashboard has a strong button called **"Open 3D Body Map"**, and the sidebar also has the same option.

As a user, I would not feel lost here.

4. Is it clear that body parts are clickable?

Mostly yes, because the 3D Body Map screen says:

"Click a body part to view or log pain."

That makes the interaction clear. The placeholder also says **"Clickable body zones"**, which helps.

But because this is low-fidelity, I cannot fully see which exact body parts are clickable yet. In the final design, I would expect the knee, ankle, hamstring, shoulder, and back areas to highlight when I hover over them.

5. What do you expect to happen after clicking a body part?

If I click on the knee, I expect the right-side panel to update with information about that body part. For example:

Selected Body Part: Left Knee

Current status

Pain level

Recovery status

Previous logs

Button to add a new log

This matches what I see in the wireframe, so the flow makes sense.

6. Is the Add Injury Log modal easy to understand?

Yes, the modal is quite clear. I understand that I can add:

Pain level

Injury status

Recovery status

Notes

The **Save Log** button is clear, and the **Cancel** button is useful.

As a soccer player, I like that it does not ask too many complicated questions. After training or a match, I would want to log pain quickly, not fill in a long medical form.

7. Are the fields in the injury log form enough, or is something missing?

The fields are good for a basic version, but I would add a few things.

I would add **activity type**, for example:

Training

Match

Gym

Recovery session

This matters because knee pain after a match feels different from knee pain after gym training.

I would also add **pain trigger**, such as:

Sprint

Shot

Landing

Tackle

Change of direction

Running

For soccer, this would be very useful because many injuries happen during specific movements.

I would also add an optional **"Can you train/play?"** field with simple options:

Yes

Limited

No

That would make the app more useful for deciding training intensity.

8. Is the dashboard useful, or does it show too much information?

The dashboard is useful. I like the cards showing:

Active injuries

Average pain level

Recovery progress

Injury risk

That gives me a quick overview.

The recent injury logs are also useful because I can quickly see if my knee pain is getting worse or better. For example, seeing pain levels 6, 7, 8, 9 tells me that something is not improving.

It does not feel like too much information, but I think the dashboard could be even better if the most urgent issue was highlighted. For example:

"Left Knee pain increased this week."

That would immediately tell me what to focus on.

9. Is the injury history timeline easy to scan?

Yes, it is quite easy to scan. The cards are clear, and I can see the body part, date, pain level, status, and note.

As a soccer player, I like that I can filter by body part, status, and date range. That would help me quickly check only knee injuries or ankle problems.

One thing I would improve is the visual difference between pain levels. Right now, all cards look quite similar. I would make high pain logs stand out more, maybe with a red border or stronger label.

10. Does the weekly report explain the data clearly?

Yes, the weekly report is clear. I like that it shows:

Average pain

New logs

Recovery progress

Risk level

Pain trend over time

Body part summary

Recovery suggestions

The sentence at the top is useful because it explains the week in simple language.

The **Smart Recovery Suggestions** section is helpful, but I would be careful with the wording. It should sound like general advice, not medical advice. For example, "Consider reducing training intensity" is good because it is not diagnosing anything.

The disclaimer at the bottom is also good.

11. Does the app feel like self-tracking instead of medical diagnosis?

Yes, it feels like self-tracking. The app uses words like pain level, recovery status, logs, progress, and weekly report. It does not feel like it is trying to diagnose an injury.

The disclaimer on the login page and weekly report helps make that clear.

I think the app should keep using wording like:

"Track pain"

"Monitor recovery"

"Consider reducing intensity"

"Consult a professional if pain continues"

That keeps it safe and realistic.

12. What would you improve first?

The first thing I would improve is making the 3D Body Map interaction more obvious. Since the 3D body is the main feature, I would make clickable body parts visually clear with hover effects, labels, or highlighted zones.

The second thing I would improve is making pain logging faster. After a match, I would want to log pain in maybe 20 seconds. A quick log option would be useful.

The third thing I would improve is adding sport-specific context, especially for soccer. For example, whether the pain happened during sprinting, shooting, tackling, or changing direction.

Things I Like

I like that the dashboard gives a quick overview.

I like that the 3D Body Map is the central feature.

I like that the injury log modal is simple.

I like that the weekly report explains trends instead of only showing numbers.

I like that the app clearly feels like self-tracking, not medical diagnosis.

Things That Confuse Me

The body map placeholder tells me body parts are clickable, but I cannot yet see which parts are clickable.

The pain trend chart is useful, but in the wireframe it is still only a placeholder, so I cannot judge how clear the final chart will be.

The difference between **Injury Status** and **Recovery Status** could maybe be explained better. For example, I would want to know if "Moderate Pain" is an

injury status or pain status.

What Would Make It Faster After Training or a Match?

I would add a **Quick Log** flow:

1. Select body part
2. Choose pain level
3. Choose activity: match/training/gym
4. Add optional note
5. Save

For soccer players, I would also add common body parts or frequent issues at the top, like:

Knee

Ankle

Hamstring

Groin

Calf

That would make logging much faster.

Top 3 Recommended Improvements

1. **Make the 3D Body Map more interactive and obvious**

Add hover states, highlighted clickable body zones, and labels for important body parts.

2. **Add sport-specific injury context**

Include fields like activity type, pain trigger, and whether the player can train/play.

3. **Improve quick logging after training or matches**

Create a faster pain log flow so users can record pain in under 30 seconds.
